## Assessment of *E. fastigata* Tree Height at Kaingaroa Cpt. 333

### Summary

A 31 month old *Eucalyptus fastigata* progeny trial growing in Kaingaroa forest was assessed for height growth. Tree health and survival was good apart from some wind toppling. Growth was fairly uniform across the trial site. Average tree height was 4.5 metres with second generation families of Oakura origin amongst the most vigorous. A full list of estimated breeding values for each family and the best individual from each family are in Appendix 3. In a few years time the trees will be assessed for tree form before the final selections are made to take forward to form the next generation.

**Authors:** Stuart Kennedy, Charlie Low, Scion

### Introduction

The trial was planted from seed collected from selections made by Mondi forest (South Africa), from first generation trials in Kaingaroa and Kinleith and from selections made in a stand of Oakura origin in Kaingaroa cpt 1227. The trial is an incomplete block design, 4 incomplete blocks per replicate, 30 replicates of single-tree plots of 125 families, 5 filler seedlots and two control seedlots.

Tree height at 31 months was measured in decimetres using height poles. A list of family means is in Appendix 2. Diameter growth is around one centimetre per metre of height, so the trees are very slender for their height compared to radiata pine. Tree growth is very good with the average height of trees now 4.5 metres, yet the trees are still 5 months short of three years old. The preceding trial, planted in Kaingaroa and Kinleith in 1979 averaged around 7 metres in height at age 5 years with the tallest trees at 13-14 metres. This could mean that early problems of inbreeding provided a high proportion of poorly grown trees in the 1979 trial.

Very little browsing by paropsis was seen and general health is excellent. Around 10% of trees were forked, although most forking was at ground level. Some toppling happened early on with the spot mounds not providing enough firm ground for the roots to stabilise the tree. The recent strong winds in March 2012 have also brought some trees down. Pigs have done some substantial digging, mainly around decaying radiata pine stumps in their search for huhu

grubs. The root systems of some trees have been exposed / damaged by pigrooting. There are some patches of blackberry that will get worse as the eucalypts won't shade it out totally. Growth of tutu is vigorous but all of the trees are well above all weeds.

### Analysis

*Eucalyptus* species can be effected by micro site changes, for this reason (where significant) data was analysed spatially to remove as much of the micro site variation as possible. Genetic parameters and breeding values were estimated (Appendix 3) for traits using mixed model equations (Appendix 1) that were solved using the software package ASReml-R.

### Discussion of Results

The Barrington Tops control seedlot performed poorly, as it did at Tylees (Kaingaroa) in the 1994 trial. The "genetic gain" seedlot comprised of 10 families that had performed well at Tylees also performed poorly (108 out of 132). At the family level, the best family (code 253 from Oakura) was 5.4 metres tall, while the worst was 3.8 metres. Survival was excellent, with the poorest survival being 87%. Families of Oakura origin, which performed well in the 1979 trials are performing well, although the odd Oakura family is poor. In general, the second generation seedlots from the 1979 trials are doing well as should be expected on a very similar site. The Mondi seedlots are not doing so well, nor are the second generation families from South African seedlots at Tylees.

Date: October 2012

An analysis by origin showed that the Tylees progenies were about 20 cm shorter than the second generation progenies from the 1979 trial and the Oakura progenies from Kaingaroa cpt 1227. The Tylees progenies had only 6% of trees with forks versus 13% the Oakura progenies. The Mondi progenies were also 20 cm shorter, with forking at 10%, while the 6 seed orchard selections from Kakarihi road were the tallest and had the lowest forking of 5%.

Growth is reasonably even across the trial (Figure 1). The trees occupy three columns between windrows. The trees in the central column were usually rather smaller than the trees on the edges of windrows that had more space to grow. The windrow effect also noted in the neighbouring *E. regnans* trial although noticeable was not considered as severe for the *E. fastigata* possibly due to the slightly slower height growth meaning that differences between columns are currently less accentuated. Following spatial analysis the residual variation (unexplained variation) (Figure 2) did not reveal such a strong linear column effect and thus did not require further analysis.

**Figure 1.** Raw height data, white boxes indicate missing trees, red boxes smallest trees and yellow boxes largest trees. Block boundaries (3 trees by 11) are indicated by the overlain grid.

**Figure 2.** Plotted residual variation following spatial analysis. Block boundaries (3 trees by 11) are indicated by the overlain grid. A faint linear trend attributed to the presence of wind rows can be seen running through the middle row (darker lines) of each block.

A list of parental breeding values for height growth estimated using model 3 (Appendix 1) are in Appendix 3. Breeding values are an estimate of the genetic merit for each tree for each trait. The trees are almost large enough to select from based on the current height assessment. Some trees may be producing seed now, but it is likely to be at least another two years before any large scale collection can be made. Before selecting the final trees to form the basis of the next generation of the breeding cycle an assessment of tree straightness and form should be made. It is of particular importance that form be assessed and selected for in *E. fastigata* due to its propensity to break out early to heavy branches. The best individual of each parent is shown in Appendix 3 so that scion material can be collected from the best individual from the better families present in the trial to form a seed orchard.

**Note.** The basic model used was as follows;  $\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{Z}_1\mathbf{a} + \mathbf{Z}_2\mathbf{r} + \mathbf{Z}_3\mathbf{r.b} + \mathbf{e}$   
 where:  $\mathbf{y}$  is the vector of individual-tree observations on a trait,  $\mathbf{b}$  is a vector of fixed effects (i.e., mean),  $\mathbf{a}$  is a vector of random additive genetic effects of individual genotypes,  $\mathbf{r}$  is a vector of random replicate effects,  $\mathbf{r.b}$  is the random interaction between replicate and block, and  $\mathbf{e}$  is a vector of random residual effects.  $\mathbf{X}$ ,  $\mathbf{Z}_1$ ,  $\mathbf{Z}_2$  and  $\mathbf{Z}_3$  are known incidence matrices relating the observations in  $\mathbf{y}$  to effects in  $\mathbf{b}$ ,  $\mathbf{a}$ ,  $\mathbf{r}$  and  $\mathbf{r.b}$  respectively. Row and column were added to the design, placing each tree in a grid enabling trees to be analysed spatially.
