DATA FROM E. REGNANS REGIMES TRIAL

This trial was planted between the 28th to 31st of August 1978 by the Murupara Womens' gang. It is located in compartments 1209 and 1210 of the Murupara subdivision of Kaingaroa Forest. The registered plot number is R01980. Seedlings were 1/0 bare rooted seedlings raised in the FRI nursery from seed which originated in Franklin, Tasmania (approximately 350 m.a.s.l.). The site had previously been occupied by P. radiata planted 1931 and logged in 1977 and 1978. Site preparation before planting included an overspraying with a mixture of Amitral/Atrazine and Simazine.

The experiment is laid out in three blocks adjacent to each other. Within each block, three groups of plots totalling 1 hectare each were planted at 625, 1100 and 2500 stems/ha. Within each of these groups the individual plots representing treatments were randomly located. Plot size is 0.09 ha each surrounded by 10 m buffer strip and this results in a total area of 0.25 ha receiving the same treatment. One exception is the treatment designed to be reduced to 50 s/ha and for this the plots are 0.24 ha in order to include sufficient crop trees to provide an adequate sample.

The silvicultural schedules were designed by the late D. Revell and had the objective of testing 11 alternatives that would cover likely options for pulpwood, sawlog or mixed objective regimes. These have been modified since to give a wider range of final crop stocking levels as this will strengthen the use of the trial data for growth modelling purposes. Details of the regimes are shown on the attached treatment schedule where it can be seen that final crop stockings range from 2500/ha to 50/ha. Both pruned and unpruned regimes are included. In 1986 a twelfth regime testing 1 lift pruning to 6.0 m was added but no data are yet available for this option.

Measurements began in July 1982 and data are presented on the attached sheets. In 1982 all heights were measured for all trees in the trial and the statistic MCH (mean crop height) refers to the average in all cases. For subsequent measurements however the MCH statistic for treatments 1 to 4 inclusive, refers to the average height of a fixed sample of 30 trees selected at random across the diameter range but in proportion to the diameter frequency distribution. From 1983 onwards the data include a figure for increment and this is the arithmetic difference between the current and previous annual measurement. The trial was first thinned in 1983 immediately after the annual measurement and the sheet headed "1983 crop element" shows the data for the crop element after thinning. The increment is the difference in growth between the two years measurement; for the crop element alone. For each treatment the data are shown separately by blocks. Note that block C which is located more towards the ridge top invariably has the poorest growth. As can be seen from the attached schedule, pruning occurred in 1982, 1983 and 1986 for those regimes where it was prescribed.
